In the prior art, many different systems are utilized to communicate with people located remotely. A typical prior art communication system would include a radio transmitter and a radio receiver. The radio receiver would be designed to receive radio waves sent from a radio transmitter. The radio receiver would then convert the radio waves into an electrical signal that is capable of being interpreted by the intended user. In order to avoid the need for sophisticated receivers and transmitters, a single low power transmitter may be used to communicate with multiple radio receivers. In the prior art, this system is known as a Frequency Modulated Radio (FM) system. Such a system could be used, for example, for transmitting distress signals to a rescue helicopter. Another type of system is a VHF radio broadcast system. This system is typically used for radio broadcasting and is capable of transmitting a low power signal which may be received with a radio receiver. The VHF system may also be used for the broadcast of television signals which are received with a radio receiver. In order to conserve power, some prior art communication systems utilize a low duty cycle signal. For example, U.S. Pat. No. 4,743,715, issued to Klouda et al. discloses a multiplexed communication system. This system sends modulated carrier signals at a low duty cycle using various digital and analog modulation techniques. A plurality of carrier signals at different frequencies are time division multiplexed to modulate a carrier signal which is then transmitted to a receiver. A single low duty cycle carrier is derived from the multiplexed carrier signal ca3bfb1094
